1. (a) [6 points] Find integers u, v such that 113u + 50v = 1.

Clearly show your steps. For full points, your process should be efficient enough to be done by hand without much arithmetic or trial and error.

- (b) [6 points] Solve the congruence $50x \equiv 3 \pmod{113}$, for the variable x. You should answer in the form of a congruence $x \equiv \cdots \pmod{\cdots}$.
- 2. [12 points] Alice and Bob perform Diffie-Hellman key exchange, with the following public parameters:

$$p = 41, g = 6.$$

Alice sends Bob the number

$$A = 26$$
,

and Bob sends Alice the number

$$B = 30.$$

Eve listens to this exchange, and manages to figure out Alice's secret integer: it is

$$a = 17$$
.

Using this information (and the mod-41 multiplication table at the back of the packet), determine Alice and Bob's shared secret S.

(It is possible to do this with only a few mod-41 multiplications; try to find an efficient method.)

3. [12 points] Alice and Bob are using the Elgamal cryptosystem, with public parameters p, g. Denote Alice's public key by A (see the summary table at the back of the exam packet).

Bob encrypts a plaintext m and sends Alice the corresponding ciphertext (c_1, c_2) . He then encrypts a plaintext n and sends Alice the corresponding ciphertext (d_1, d_2) .

Eve knows that numbers p, g, A, and she also intercepts both ciphertexts. She is also able to determine the message m (perhaps because it is a standard email header). Finally, she observes that Bob has not randomized his ephemeral keys well! In particular, she notices the following relationship between the ciphertexts:

$$d_1 \equiv c_1^{-1}g \pmod{p}.$$

Using this information, solve for the second ciphertext n in terms of numbers that Eve knows.

4. [12 points] Suppose that p is a prime number, satisfying $p \equiv 2 \pmod{3}$, and that $y \in \mathbb{Z}/p\mathbb{Z}$. Write a Python function cuberoot(y,p) that returns a solution $x \in \mathbb{Z}/p\mathbb{Z}$ to the congruence $x^3 \equiv y \pmod{p}$, and prove that the value returned by your function does indeed solve this congruence.

You may assume that you have already written an efficient function modinv(a, m) computing a^{-1} (mod m), and you may use Python's built-in function pow(a, e, m) returning a^e (mod m). For full points, your solution should be practical for cryptographically large integers (e.g. thousands of bits).

Public parameter creation											
A trusted party chooses and publishes a (large) prime p											
and an integer g having large prime order in \mathbb{F}_p^* .											
Private computations											
Alice Bob											
Choose a secret integer a .	Choose a secret integer b.										
Compute $A \equiv g^a \pmod{p}$.	Compute $B \equiv g^b \pmod{p}$.										
Public exchange of values											
Alice sends A to Bob \longrightarrow A											
$B \leftarrow$ Bob sends B to Alice											
Further private	e computations										
Alice	Bob										
Compute the number $B^a \pmod{p}$.	Compute the number $A^b \pmod{p}$.										
The shared secret value is $B^a \equiv (g^b)^a \equiv g^{ab} \equiv (g^a)^b \equiv A^b \pmod{p}$.											

Table 2.2: Diffie–Hellman key exchange

Public parameter creation											
A trusted party chooses and publishes a large prime p											
and an element g modulo p of large (prime) order.											
Alice	Bob										
Key creation											
Choose private key $1 \le a \le p-1$.											
Compute $A = g^a \pmod{p}$.											
Publish the public key A .											
Encryption											
	Choose plaintext m .										
	Choose random element k .										
	Use Alice's public key A										
	to compute $c_1 = g^k \pmod{p}$										
	and $c_2 = mA^k \pmod{p}$.										
	Send ciphertext (c_1, c_2) to Alice.										
Decryption											
Compute $(c_1^a)^{-1} \cdot c_2 \pmod{p}$.											
This quantity is equal to m .
